

Figure 4 | Stability is a property of the observable and its measurement protocol

Protocol A.1 replaces the archived float32 perturbation probe with a frozen five-seed uniform-noise probe at the same float32 L-infinity amplitude.

A | Probe definition materially changes the inferential floor B | Eligibility follows directly from the A.1 floor C | The protocol correction is strongly material dependent

Paired comparison across 254 materials; each line is one density floor. A material is eligible at tau only when its uncompressed stability floor is higher than the A.1 floor. The protocol correction cannot recover the A.1 identifiability floor

Protocol A remains archived and unchanged. All headline eligibility and certification statistics use the frozen Protocol A.1 definition.
