

Supplementary Figure S6 | Realized-distortion matching conclusions are robust to the caliper choice

The primary 0.10-dex analysis balances support and distortion similarity; ZFP retains lower re-derived Bader error than SZ3/SPERR after matching, whereas SZ3 and SPERR remain similar.

A, re-derived Bader-error ratios across all pre-specified calipers; values below one favour the numerator codec. B, material common support. C, residual realized-L-infinity imbalance among matched pairs. Matching controls scalar maximum perturbation but not the full geometry of the error field; the residual codec effect is consistent with an error-structure contribution but does not identify a unique spatial invariant.
