

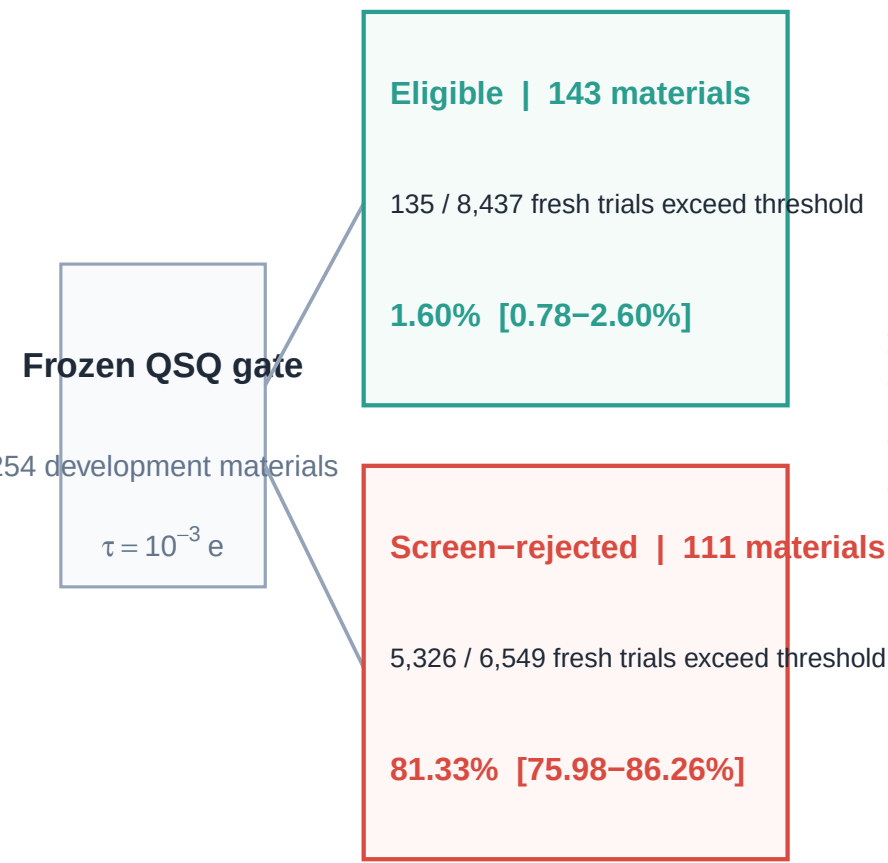

Figure 3 | QoI Stability Qualification prospectively stratifies downstream numerical risk

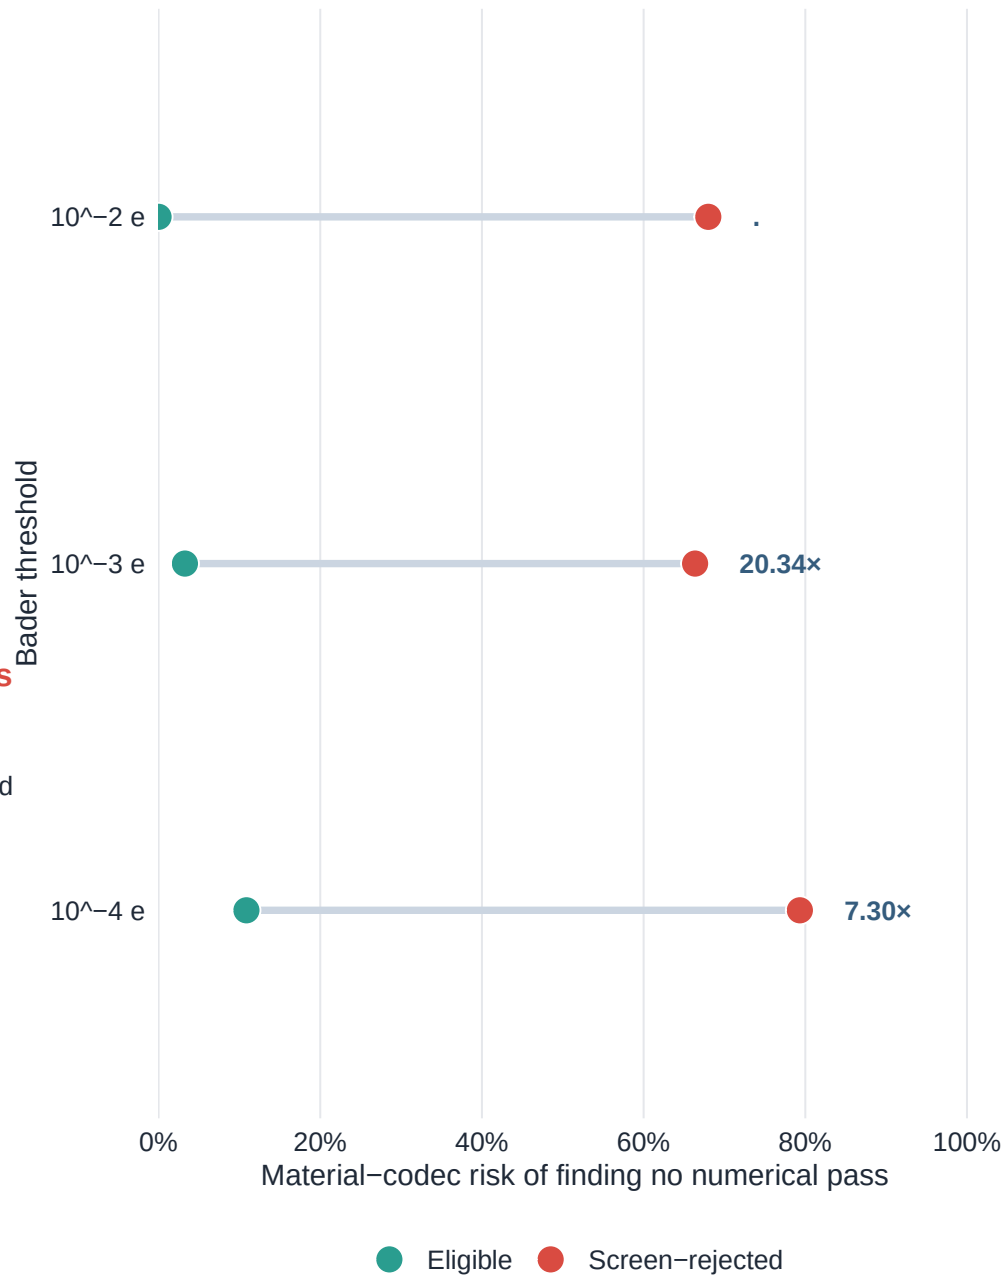

A Frozen gate predicts fresh perturbation risk

Primary endpoint; 59 pre-registered unseen streams per material

B Risk persists after equalizing codec search opportunity

1,332/1,332 additive tight-ladder reconstructions succeeded

C Prospective discrimination generalizes across thresholds

14,986/14,986 fresh trials; intervals resample materials, not trials

Primary result

At 10⁻³ e, the frozen five-seed QSQ gate retains 56.3% of materials while separating 1.60% fresh exceedance risk in admitted materials from 81.33% in screen-rejected materials (50.83×).
This is prospective risk stratification under the declared iid-uniform model – not a worst-case stability guarantee.
